The use of petroleum products in the process of its production and application is harmful to the environment, to people who work with petroleum products and to the ecosystem. Jan 12, 2020 6:14 pm. Some other devices, such as the washing machine, refrigerator and many others, which consume or produce significant amounts of energy, are not included in the following calculation. The present invention relates to systems and methods for treating tissue, and more specifically to systems and methods for treating tissue using microwave energy. Treatment of various tissues within the body presents significant challenges. For example, one common procedure used for treating certain ailments is the implantation of one or more electrical leads into the tissue. For example, transvenous implantable cardioverter defibrillators (ICDs) can include pacing and defibrillation capabilities. Such transvenous ICDs have been used to correct cardiac arrhythmias and other conditions and are able to operate for years without patient intervention. The tissue to be treated in this example can include muscle or myocardial tissue, including myocardial tissue within the right ventricular chamber of the heart. In this example, the ICD leads can be introduced into the heart through the superior vena cava, the right atrium, the atrial septum, and/or the apex of the right ventricle. In such procedures, microwave energy can be used to thermally heat the tissue within the heart. Microwave energy has certain advantages over other heating techniques, including its ability to heat larger volumes of tissue more quickly without the risk of charring, burning, and carbonization of the tissue. However, microwave energy can have certain disadvantages, including the inability to heat very small volumes of tissue, as well as the need for precise targeting of the energy to the tissue. For example, the microwaves can be emitted from a tissue-contacting surface of the device, which can only target the tissue 2d92ce491b
